Abstract

Graph theory is helpful in various practical problems solving in circuit or network analysis and data structure. It leads to graph practically not possible to analyse without the aid of computer. In electrical engineering the word is used for edge, node for vertex and loop for circuit. An electrical network is the set of electronic components i.e. resistors, inductors and capacitors etc. Electric network analysis and synthesis are the study of network topology. Electric network problem can be represented by drawing graphs. In this paper, we present a circuit network in the concept of graph theory application and how to apply graph theory to model the circuit network.

Keywords: Graph theory, Adjacency matrix, Electrical circuit and analysis

Introduction: A connected graph without closed path i.e. tree was implemented by G.Kirchhoff in 1847 and he employed graph theoretical concept in the calculation of currents in network or circuits and was improved upon J.C.Maxwell in 1892.[4] Ever since, graph theory has been applied in electrical network analysis .An electrical network is a collection of components and device interconnected electrically .The network components are idealized of physical device and system, in order to for them to represent several properties, they must obey the Kirchhoff's law of currents and voltage.[1]A graph representation of electrical network in terms of line segments or arc called edges or branches and points called vertices or terminals.

Basic Definition of Graph Theory

Graph: A graph G is defined by $(V; E)$ where the elements of the set V are called vertices of graph G and the elements of the set E are called edges of graph G . A vertex is represented by a dot and an edge is represented by line segment connecting the dots associated with the edge.

Directed Graph: If the edges of a graph direct one vertex to the other vertex, then the graph is called as a directed graph. Otherwise graph is called an undirected graph. In an undirected graph $G = (V, E)$, the edges are unordered pairs, and each edge e_1 in E is associated with two vertices v_1 and v_2 , and it is written as either $e_1 = (v_1, v_2)$ or $e_1 = (v_2, v_1)$. But, In a directed graph, each edge e_1 in E is associated with an ordered pairs of vertices (v_1, v_2) and it is denoted the directed edge e_1 from v_1 to v_2 . Two vertices v_1 and v_2 of a graph are adjacent, if there is an edge, $v_1 v_2$ connecting them, then vertices are then considered incident to the edge $v_1 v_2$.

Analysis of Electrical Circuit: Ohm's law states that for an edge 'e', the current flowing across that edge e is given by $i_e = V/R$. We see that this means that $i_{\{uv\}} = -i_{\{vu\}}$ and the negative current as positive currents flowing the different way. The weight of an edge as the conductance of that edge, which Both the resistance and conductance are independent of edge such as $r(vu) = r(uv)$ and $c(uv) = c(vu)$.

Kirchhoff's Circuit Law: Kirchhoff's voltage law states that for a closed loop $\sum V = 0$ or $\sum V$ rise is equal to $\sum V$ drops. The total resistance of 'n' resistors in series is $R_T = R_1 + R_2 + R_3 + \dots + R_n$ and the total power are $P_T = P_1 + P_2 + P_3 + \dots + P_n$ in series, So that the same current flows through all the components but a different potential voltage can exist across every one. In parallel, so that the same potential difference exists across every components but each component may carry a different current.

Representation of circuit and its graph: A graph model is used to represented circuit network in graph by tracing the nodes of the circuit and edges contain in circuit.

Here is the graph of the circuit

Figure 2

A circuit is a path which ends at the vertex it begins. An electric circuit is a closed loop formed by source, wires, load, and a switch, when switch is turned on the electrical circuit is complete and current flows from negative terminals of the power source. An electrical circuit is categories in to three type namely series, parallel and series and parallel circuit. The representation of graph in circuit network are one of the type of representation of graph in which the current flows in circuit and present the linking of connection. Network graph between resistors series and parallel connection are determined in the circuit. The representation is

Figure 3

The schematic figure of the electric circuit is as follows,

Graph Representation of Matrix: A graph can actually be represented using matrices method the two of the most widely used matrices for graph representation is adjacency and incidence matrices. An adjacency matrix is a square matrix in which each row and column is represented by a vertex. Consider figure 4, as an example it has three vertices $V = \{ R1, R2, R3 \}$ this mean that the square matrix must be 3×3 let each row and column is represented by each of the six vertices in V .

	R1	R2	R3
R1	0	1	0
R2	1	0	1
R3	0	1	0
R4	0	0	1
R5	0	0	0
R6	0	1	1

$$G = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & 1 \end{bmatrix}$$

Conclusion: In this research we focus on the application of graph theory to electrical network analysis and matrix approach as an electrical network analysis. Graph theory is a very interesting topic in mathematics due to numerous applications in various fields especially in computer and electrical engineering. We use the graph theory concept and techniques that we have developed to study electrical networks. Thus, graph theory has more practical application particulars in solving electric network.
